Divide and Conquer Optimization

• The problem used here as an example requires that you know Prefix Sums as an orthogonal part of the problem.

- The problem used here as an example requires that you know Prefix Sums as an orthogonal part of the problem.
- The idea is to compute all prefix sums of the array.

- The problem used here as an example requires that you know Prefix Sums as an orthogonal part of the problem.
- The idea is to compute all prefix sums of the array.
- Suppose you have an array of integers A_0, A_1, \dots, A_{N-1} .

- The problem used here as an example requires that you know Prefix Sums as an orthogonal part of the problem.
- The idea is to compute all prefix sums of the array.
- Suppose you have an array of integers $A_0, A_1, \ldots, A_{N-1}$.
- Let $S(i,j) = A_i + A_{i+1} + ... + A_{j-1} + A_j$.

- The problem used here as an example requires that you know Prefix Sums as an orthogonal part of the problem.
- The idea is to compute all prefix sums of the array.
- Suppose you have an array of integers $A_0, A_1, \ldots, A_{N-1}$.
- Let $S(i,j) = A_i + A_{i+1} + ... + A_{j-1} + A_j$.
- Compute and store all values of S(0,j) for all j such that $0 \le j < N$.

- The problem used here as an example requires that you know Prefix Sums as an orthogonal part of the problem.
- The idea is to compute all prefix sums of the array.
- Suppose you have an array of integers $A_0, A_1, \ldots, A_{N-1}$.
- Let $S(i,j) = A_i + A_{i+1} + ... + A_{j-1} + A_j$.
- Compute and store all values of S(0,j) for all j such that $0 \le j < N$.
- Now you can compute S(i,j) = S(0,j) S(0,i-1) in constant time for any i and j.

• There are $1 \leq N \leq 8000$ prisoners, each in their own cell, and $1 \leq G \leq 3000$ guards.

- There are $1 \leq N \leq 8000$ prisoners, each in their own cell, and $1 \leq G \leq 3000$ guards.
- Each prisoner i has an intelligence $1 \le S_i \le 10^9$.

- There are $1 \leq N \leq 8000$ prisoners, each in their own cell, and $1 \leq G \leq 3000$ guards.
- Each prisoner i has an intelligence $1 \le S_i \le 10^9$.
- Each jail cell is assigned to exactly one guard.

- There are $1 \leq N \leq 8000$ prisoners, each in their own cell, and $1 \leq G \leq 3000$ guards.
- Each prisoner i has an intelligence $1 \le S_i \le 10^9$.
- Each jail cell is assigned to exactly one guard.
- Each guard can only watch over a contiguous range of prisoners.

- There are $1 \le N \le 8000$ prisoners, each in their own cell, and $1 \le G \le 3000$ guards.
- Each prisoner i has an intelligence $1 \le S_i \le 10^9$.
- Each jail cell is assigned to exactly one guard.
- Each guard can only watch over a contiguous range of prisoners.
- If the guard watching prisoner i is watching over k cells, then the prisoner's escaping potential is kS_i .

- There are $1 \leq N \leq 8000$ prisoners, each in their own cell, and $1 \leq G \leq 3000$ guards.
- Each prisoner i has an intelligence $1 \le S_i \le 10^9$.
- Each jail cell is assigned to exactly one guard.
- Each guard can only watch over a contiguous range of prisoners.
- If the guard watching prisoner i is watching over k cells, then the prisoner's escaping potential is kS_i .
- Your goal is to assign the cells to guards in a way that minimizes the total escaping potential over all prisoners.

 \bullet Let $\mathrm{dp}(j,k)$ denote the optimal answer up to the $j\mathrm{th}$ prisoner with k guards.

- Let $\mathrm{dp}(j,k)$ denote the optimal answer up to the jth prisoner with k guards.
- Let $C(i,j) = (j-i+1) \cdot \sum_{k=i}^{j} S_k$.

- Let $\mathrm{dp}(j,k)$ denote the optimal answer up to the jth prisoner with k guards.
- Let $C(i,j) = (j-i+1) \cdot \sum_{k=i}^{j} S_k$.
- Then we have dp(i, 1) = C(0, i) as a base case.

- Let dp(j, k) denote the optimal answer up to the jth prisoner with k guards.
- Let $C(i,j) = (j-i+1) \cdot \sum_{k=i}^{j} S_k$.
- Then we have dp(i, 1) = C(0, i) as a base case.
- When assigning a new guard, lets fix the end index of the segment. We must then find the optimal starting index.

- Let dp(j, k) denote the optimal answer up to the jth prisoner with k guards.
- Let $C(i,j) = (j-i+1) \cdot \sum_{k=i}^{j} S_k$.
- Then we have dp(i, 1) = C(0, i) as a base case.
- When assigning a new guard, lets fix the end index of the segment. We must then find the optimal starting index.
- We try all start indices

$$dp(j,k) = \min_{0 \le i < j} (dp(i,k-1) + C(i+1,j))$$

- Let dp(j, k) denote the optimal answer up to the jth prisoner with k guards.
- Let $C(i,j) = (j-i+1) \cdot \sum_{k=i}^{j} S_k$.
- Then we have dp(i, 1) = C(0, i) as a base case.
- When assigning a new guard, lets fix the end index of the segment. We must then find the optimal starting index.
- We try all start indices

$$dp(j,k) = \min_{0 \le i < j} (dp(i,k-1) + C(i+1,j))$$

 \bullet Our state space is $\mathcal{O}(NG)$ and each state can be computed in $\mathcal{O}(N)$ time.

- Let dp(j, k) denote the optimal answer up to the jth prisoner with k guards.
- Let $C(i,j) = (j-i+1) \cdot \sum_{k=i}^{j} S_k$.
- Then we have dp(i, 1) = C(0, i) as a base case.
- When assigning a new guard, lets fix the end index of the segment. We must then find the optimal starting index.
- We try all start indices

$$dp(j,k) = \min_{0 \le i < j} (dp(i,k-1) + C(i+1,j))$$

- \bullet Our state space is $\mathcal{O}(NG)$ and each state can be computed in $\mathcal{O}(N)$ time.
- Time complexity is $\mathcal{O}(N^2G)$, which is too slow.

Implementation - Initial Definitions

```
#include <bits/stdc++.h>
using namespace std;
typedef long long 11;
const 11 INF = 80'000'000'000'000'000LL:
ll arr[8000];
11 prefix_sum[8001];
ll mem[3001][8001];
ll range_sum(int left, int right) {
   return prefix_sum[right] - prefix_sum[left-1];
}
11 cost(ll left, ll right) {
   return range_sum(left, right) * (right - left + 1LL);
```

Naive Implementation - Computing Each Layer

Naive Implementation - Main

```
int main()
{
    int n, g;
    cin >> n >> g;
    prefix_sum[0] = 0;
    for (int i = 0; i < n; i++) {
        cin >> arr[i];
        prefix_sum[i+1] = prefix_sum[i] + arr[i];
    for (int i = 0; i < n; i++) {
        mem[0][i] = cost(0, i);
    for (int guards = 2; guards <= g; guards++) {</pre>
        compute(guards - 1, n);
    cout << mem[g - 1][n - 1] << endl;
    return 0;
}
```

• Let $\mathrm{opt}(j,k)$ be the optimal splitting point, or the value of i which minimizes the previous expression.

- Let opt(j, k) be the optimal splitting point, or the value of i which minimizes the previous expression.
- We note that $\operatorname{opt}(j-1,k) \leq \operatorname{opt}(j,k) \leq \operatorname{opt}(j+1,k)$.

- Let opt(j, k) be the optimal splitting point, or the value of i which minimizes the previous expression.
- We note that $\operatorname{opt}(j-1,k) \leq \operatorname{opt}(j,k) \leq \operatorname{opt}(j+1,k)$.
- This allows us to divide and conquer.

- Let opt(j, k) be the optimal splitting point, or the value of i which minimizes the previous expression.
- We note that $\operatorname{opt}(j-1,k) \leq \operatorname{opt}(j,k) \leq \operatorname{opt}(j+1,k)$.
- This allows us to divide and conquer.
- First compute dp(N/2, k) and note the value of opt(N/2, k).

- Let opt(j, k) be the optimal splitting point, or the value of i which minimizes the previous expression.
- We note that $\operatorname{opt}(j-1,k) \leq \operatorname{opt}(j,k) \leq \operatorname{opt}(j+1,k)$.
- This allows us to divide and conquer.
- First compute dp(N/2, k) and note the value of opt(N/2, k).
- With that value in mind, compute dp(N/4, k) and dp(3N/4, k).

- Let opt(j, k) be the optimal splitting point, or the value of i
 which minimizes the previous expression.
- We note that $\operatorname{opt}(j-1,k) \leq \operatorname{opt}(j,k) \leq \operatorname{opt}(j+1,k)$.
- This allows us to divide and conquer.
- First compute dp(N/2, k) and note the value of opt(N/2, k).
- With that value in mind, compute dp(N/4, k) and dp(3N/4, k).
- Repeat this process, computing the left and right side, tracking the minimum and maximum possible value of $\operatorname{opt}(j,k)$.

• Let l and r be the values we're tracking such that $l \leq \operatorname{opt}(j, k) \leq r$.

- Let l and r be the values we're tracking such that $l \leq \operatorname{opt}(j,k) \leq r.$
- At each step we iterate from l to r. Doesn't look like we've made improvements...

- Let l and r be the values we're tracking such that $l \leq \operatorname{opt}(j,k) \leq r.$
- At each step we iterate from l to r. Doesn't look like we've made improvements...
- Note the level of the recursion, so level 1 is where we compute j=N/2, level 2 is where we compute j=N/4 and j=3N/4, and so on.

- Let l and r be the values we're tracking such that $l \leq \operatorname{opt}(j,k) \leq r.$
- At each step we iterate from l to r. Doesn't look like we've made improvements...
- Note the level of the recursion, so level 1 is where we compute j=N/2, level 2 is where we compute j=N/4 and j=3N/4, and so on.
- There are at most $\mathcal{O}(\log N)$ levels.

- Let l and r be the values we're tracking such that $l \leq \operatorname{opt}(j,k) \leq r.$
- At each step we iterate from l to r. Doesn't look like we've made improvements...
- Note the level of the recursion, so level 1 is where we compute j=N/2, level 2 is where we compute j=N/4 and j=3N/4, and so on.
- There are at most $\mathcal{O}(\log N)$ levels.
- At each level we will do $\mathcal{O}(N)$ work, since there is no overlap for values of j at the same level.

- Let l and r be the values we're tracking such that $l \leq \operatorname{opt}(j,k) \leq r.$
- At each step we iterate from l to r. Doesn't look like we've made improvements...
- Note the level of the recursion, so level 1 is where we compute j=N/2, level 2 is where we compute j=N/4 and j=3N/4, and so on.
- There are at most $\mathcal{O}(\log N)$ levels.
- At each level we will do $\mathcal{O}(N)$ work, since there is no overlap for values of j at the same level.
- Note it does not matter how balanced $\mathrm{opt}(j,k)$ is, we always do linear work at a level.

- Let l and r be the values we're tracking such that $l \leq \operatorname{opt}(j,k) \leq r$.
- ullet At each step we iterate from l to r. Doesn't look like we've made improvements...
- Note the level of the recursion, so level 1 is where we compute j=N/2, level 2 is where we compute j=N/4 and j=3N/4, and so on.
- There are at most $\mathcal{O}(\log N)$ levels.
- At each level we will do $\mathcal{O}(N)$ work, since there is no overlap for values of j at the same level.
- Note it does not matter how balanced ${\rm opt}(j,k)$ is, we always do linear work at a level.
- Time complexity is now $\mathcal{O}(NG \log N)$, so fast enough.

Optimized Implementation - Computing Each Layer

```
void compute(int level, int l, int r, int optl, int optr) {
    if (1 > r) return;
    int mid = (1+r)/2;
    pair<11, int> best = {INF, -1};
    for (int k = optl; k <= min(mid, optr); k++) {</pre>
        best = min(best.
            \{(k ? mem[level - 1][k - 1] : OLL) + cost(k, mid), k\});
    mem[level][mid] = best.first;
    int opt = best.second;
    compute(level, 1, mid-1, optl, opt);
    compute(level, mid+1, r, opt, optr);
```

Optimized Implementation - Main

```
int main()
{
    int n, g;
    cin >> n >> g;
    prefix_sum[0] = 0;
    for (int i = 0; i < n; i++) {
        cin >> arr[i];
        prefix_sum[i+1] = prefix_sum[i] + arr[i];
    for (int i = 0; i < n; i++) {
        mem[0][i] = cost(0, i);
    for (int guards = 2; guards <= g; guards++) {</pre>
        compute(guards-1, 0, n-1, 0, n-1);
    cout << mem[g-1][n-1] << endl;
    return 0;
}
```

• When are the optimal splitting points are monotonic?

- When are the optimal splitting points are monotonic?
- \bullet When the cost function C satisfies the quadrangle inequality!

- When are the optimal splitting points are monotonic?
- ullet When the cost function C satisfies the quadrangle inequality!
- $\bullet \mbox{ When } C(a,c) + C(b,d) \leq C(a,d) + C(b,c) \mbox{ for all } \\ a < b < c < d.$

- When are the optimal splitting points are monotonic?
- ullet When the cost function C satisfies the quadrangle inequality!
- $\bullet \mbox{ When } C(a,c) + C(b,d) \leq C(a,d) + C(b,c) \mbox{ for all } \\ a < b < c < d.$
- Intuitively, this means longer segments are worse than shorter segments.

- When are the optimal splitting points are monotonic?
- When the cost function C satisfies the quadrangle inequality!
- $\bullet \mbox{ When } C(a,c) + C(b,d) \leq C(a,d) + C(b,c) \mbox{ for all } \\ a < b < c < d.$
- Intuitively, this means longer segments are worse than shorter segments.
- It is usually not that difficult to prove the quadrangle inequality holds when it does.

- When are the optimal splitting points are monotonic?
- When the cost function C satisfies the quadrangle inequality!
- $\bullet \mbox{ When } C(a,c) + C(b,d) \leq C(a,d) + C(b,c) \mbox{ for all } \\ a < b < c < d.$
- Intuitively, this means longer segments are worse than shorter segments.
- It is usually not that difficult to prove the quadrangle inequality holds when it does.
- Once you've proven it for a DP pattern like shown before, you know you can use this method.

- When are the optimal splitting points are monotonic?
- When the cost function C satisfies the quadrangle inequality!
- $\bullet \ \mbox{When} \ C(a,c) + C(b,d) \leq C(a,d) + C(b,c) \ \mbox{for all} \\ a < b < c < d.$
- Intuitively, this means longer segments are worse than shorter segments.
- It is usually not that difficult to prove the quadrangle inequality holds when it does.
- Once you've proven it for a DP pattern like shown before, you know you can use this method.
- The Convex Hull Trick can often be used in the same tasks to which this method applies.

Try on these problems!

- Guards
- Split the Sequences (Coming to Kattis soon!)
- Partition Game
- The Bakery
